morphological image processing

morphological image processing

morphological reconstruction

Morphological reconstruction:

- Processing is based on two images, a marker and a mask, rather than one image and a structuring element.
- Processing repeats until stability (the image no longer changes).
- Processing is based on the concept of connectivity, rather than a structuring element

Examples:

1. pixel connectivity
2. flood-fill operations
3. peaks and valleys

```

Two-Dimensional Connectivities		
4-connected	Pixels are connected if their edges touch. This means that a pair of adjoining pixels are part of the same object only if they are both on and are connected along the horizontal or vertical direction.	
8-connected	Pixels are connected if their edges or corners touch. This means that if two adjoining pixels are on, they are part of the same object, regardless of whether they are connected along the horizontal, vertical, or diagonal direction.	
Three-Dimensional Connectivities		
6-connected	Pixels are connected if their faces touch.	 6 faces
18-connected	Pixels are connected if their faces or edges touch.	 6 faces + 12 edges
26-connected	Pixels are connected if their faces, edges, or corners touch.	 6 faces + 12 edges + 8 corners

distance transforms

Distance Metric	Description	Illustration
Euclidean	The Euclidean distance is the straight-line distance between two pixels.	 Image  Distance transform
City Block	The city block distance metric measures the path between the pixels based on a 4-connected neighborhood. Pixels whose edges touch are 1 unit apart; pixels diagonally touching are 2 units apart.	 Image  Distance transform
Chessboard	The chessboard distance metric measures the path between the pixels based on an 8-connected neighborhood. Pixels whose edges or corners touch are 1 unit apart.	 Image  Distance transform
Quasi-Euclidean	The quasi-Euclidean metric measures the total Euclidean distance along a set of horizontal, vertical, and diagonal line segments.	 Image  Distance transform

registration

MRI

PET & MRI

registration

registration

Applications:

intramodality (T1-to-T1, PET-to-PET,...)

- motion correction
- group analysis
- comparative morphometry
- labeling

intermodality (T2-to-T1, PET-to-T1,...)

- group analysis
- multispectral analysis
- labeling

registration

Registration involves:

1. Similarity metric: (n)CR, SSD, MSD, (n)CC, MI,...
2. **Transformation** model: affine, piecewise linear, nonlinear,...
3. Regularization method: multi-resolution/scale, Gaussian blur,...
4. Optimization strategy: simplex, gradient descent,...
5. Interpolation type: nearest-neighbor, trilinear, cubic, sinc,...

transformation matrices

Scale

For scaling (that is, enlarging or shrinking), we have $x' = s_x \cdot x$

and $y' = s_y \cdot y$. The matrix form is:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} s_x & 0 \\ 0 & s_y \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

transformation matrices

Rotation

For rotation by an angle θ counterclockwise about the origin, the functional form is $x' = x\cos\theta - y\sin\theta$ and $y' = x\sin\theta + y\cos\theta$. Written in matrix form, this becomes:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Similarly, for a rotation clockwise about the origin, the functional form is $x' = x\cos\theta + y\sin\theta$ and $y' = -x\sin\theta + y\cos\theta$ and the matrix form is:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

transformation matrices

Shear

For shear mapping (visually similar to slanting), there are two possibilities. For a shear parallel to the x axis has $x' = x + ky$ and $y' = y$; the shear matrix, applied to column vectors, is:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & k \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

A shear parallel to the y axis has $x' = x$ and $y' = y + kx$, which has matrix form:

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ k & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

transformation matrices

Affine: Translation

To represent affine transformations (linear + translation) with matrices, we must use homogeneous coordinates. This means representing a 2-vector (x, y) as a 3-vector $(x, y, 1)$. The functional form $x' = x + t_x$; $y' = y + t_y$ of translation is:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & t_x \\ 0 & 1 & t_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} .$$

Affine: Rotation

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta & 0 \\ \sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} .$$

transformation matrices

degrees of freedom

- 6 dof: 3 translations, 3 rotations (x,y,z) “rigid-body”
- 7 dof: 3 translations, 3 rotations, 1 global scale
- 9 dof: 3 translations, 3 rotations, 3 scales
- 12 dof: 3 translations, 3 rotations, 3 scales, 3 shears
- >12: nonlinear transformation

example: bidirectional diffeomorphism

homeomorphism: continuous mapping and inverse, but not deformation (trefoil knot, circle)

diffeomorphism: bijective map from manifold M to N and its inverse are differentiable

Jacobian matrix: representation of a differential, an $n \times n$ matrix of first order partial derivatives whose entry in the i -th row and j -th column is $\partial f_i / \partial x_j$. The Jacobian can be thought of as describing the amount of "stretching" that a transformation imposes.
